# Roadmaps

Basic idea: Capture the connectivity of the free space by a graph.

# Roadmap Definition 1

- General
  - A roadmap is graph where nodes correspond to configurations and edges correspond to collision free paths between configurations.

# Roadmap Definition 2

- A union of one-dimensional curves is a roadmap, RM, if for all  $q_{start}$  and  $q_{goal}$  in  $Q_{free}$  that can be connected the following holds
  - Accessibility: There exists a path from  $q_{start}$  to some  $q_{start}'$  in RM
  - Departability: There exists a path from  $q_{goal}$  to some  $q_{goal}'$  in RM
  - Connectivity: There exists a path in RM between  $q_{start}'$  and  $q_{end}'$

# Path Planning using a Roadmap

- Build the Roadmap
- Connect  $q_{\text{start}}$  and  $q_{\text{goal}}$  to  $q_{\text{start}}'$  and  $q_{\text{end}}'$  both belonging to the roadmap.
- Find a path between  $q_{\text{start}}'$  and  $q_{\text{end}}'$
- What is the hard part here?
- Given a roadmap according to definition 2, what are the properties of the planner? 

# Building a Roadmap

- Grid sampling
- Visibility Graph
- Voronoi Diagram
- Cannys roadmap method
- Probabilistic roadmaps (to be discussed later in the course)

# Building a Roadmap

- **Grid sampling**
- Visibility Graph
- Voronoi Diagram
- Cannys roadmap method

# Grid Sampling

- Divide the space into a grid.
- Create a node for each collision free cell.
- Connect all neighboring collision free cells (either as 4 or 8 connected)

# Grid Sampling

- Divide the space into a grid.
- Create a node for each collision free cell.
- Connect all neighboring collision free cells (either as 4 or 8 connected)

## Pros and cons?

# Building a Roadmap

- Grid sampling
- **Visibility Graph**
- Voronoi Diagram
- Cannys roadmap method

# Visibility Graph

- Assumes all obstacles are polygons
- Nodes in the graph are vertices of the obstacles.
- Nodes are connected if
  - They are already connected by an edge on the obstacle.
  - The line segment joining them is collision free.

# Visibility Graph

- We may include the initial and goal configurations in the same way.
- The algorithm for constructing the roadmap can be done in  $O(N^3)$ 
  - $N$  is the total number of vertices
  - Each have  $O(N)$  neighbor candidates.
  - Checking each candidate is  $O(N)$  because there are  $O(N)$  edges on the polygon to check collision against.

# Visibility Graph

- **Discuss properties and pros and cons.**

# Visibility Graph

- Discuss properties and pros and cons.
- Pros
  - Gives the shortest possible path.
  - Small number of nodes (for simple obstacles)
  - Complete roadmap
- Cons
  - Goes close to obstacles
  - Requires polygons as obstacles.
  - May have many points
  - Many redundant edges

# Reduced Visibility Graph

- Define supporting and separating lines.
  - Supporting: Tangent to two obstacles both on the same side of the line.
  - Separating: Tangent to two obstacle on either side of the line.
- **Only** use those edges which corresponds to either a **separating** or **supporting** line

# Reduced Visibility Graph - Exercise

- Define supporting and separating lines.
- Only use those edges which corresponds to either a separating or supporting line
- Use the principle to update the visibility roadmap

# Building a Roadmap

- Grid sampling
- Visibility Graph
- **Voronoi Diagram**
- Cannys roadmap method

# Voronoi Diagram

# Basic Definitions

- Point to Obstacle Distance

$$d_i^x(q) = \min_{c \in QO_i} d(q, c)$$

- Gradient

$$\nabla d_i^x(q) = \frac{q - c}{d(q, c)}$$

# Basic Definitions

- Points within line of sight

$$C_i(x) = \{c \in QO_i : \forall t \in [0,1], x(1-t) + ct \in Q_{free}\}$$

- Visible distance function:

$$d_i(x) = \begin{cases} \min_{c \in QO_i} d(x, c) & \text{if } c \in C_i(x) \\ \infty & \text{otherwise} \end{cases}$$

- Multiple objects

$$D(x) = \min_i d_i(x)$$

# Equidistant for Two Objects

- Equidistant surface
- $S_{ij} = \{q \in Q_{free} | d_i(q) - d_j(q) = 0\}$

# Equidistant for with Multiple Objects

- In case of multiple obstacles
- $F_{ij} = \{q \in S_{ij} | d_i(q) \leq d_k(q) \forall k\}$

# Generalized Voronoi Diagram

- Definition of Generalized Voronoi Diagram

$$GVD = \bigcup_i \bigcup_j F_{ij}$$

# Roadmaps with Generalized Voronoi Diagrams

- How to interpret a Voronoi Diagram as a roadmap?

# Roadmaps with Generalized Voronoi Diagrams

- Will the roadmap satisfy the requirements of
  - Accessibility
  - Departability
  - Connectivity

# Relation between the Brushfire Algorithm and the Voronoi Diagram

# Building a Roadmap

- Grid sampling
- Visibility Graph
- Voronoi Diagram
- **Cannys roadmap method**

# Silhouette Methods

- Canny's Roadmap Algorithm
  - Works for obstacles defined a polynomials

# Canny's Roadmap Algorithm

- Define a direction for a sweeping slice

# Canny's Roadmap Algorithm

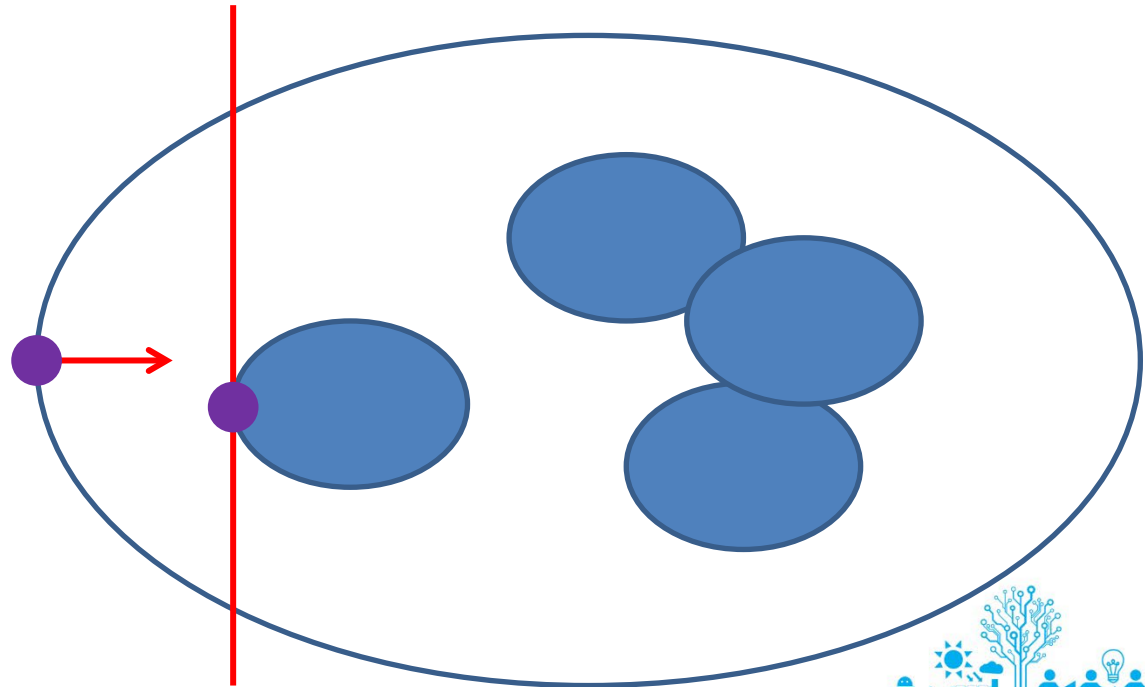

- Mark all points where the number of contours intersecting changed

# Canny's Roadmap Algorithm

- Mark all points where the number of contours intersecting changed

# Canny's Roadmap Algorithm

- Mark all points where the number of contours intersecting changed

# Canny's Roadmap Algorithm

- Mark all "critical points" where the number of contours intersecting changed

# Canny's Roadmap Algorithm

- Create connections to the outer boundary through the critical points.

# Canny's Roadmap Algorithm

- Keep the lines which
  - Are not colliding with obstacles (only tangent to)
  - The inner part of lines going through obstacles

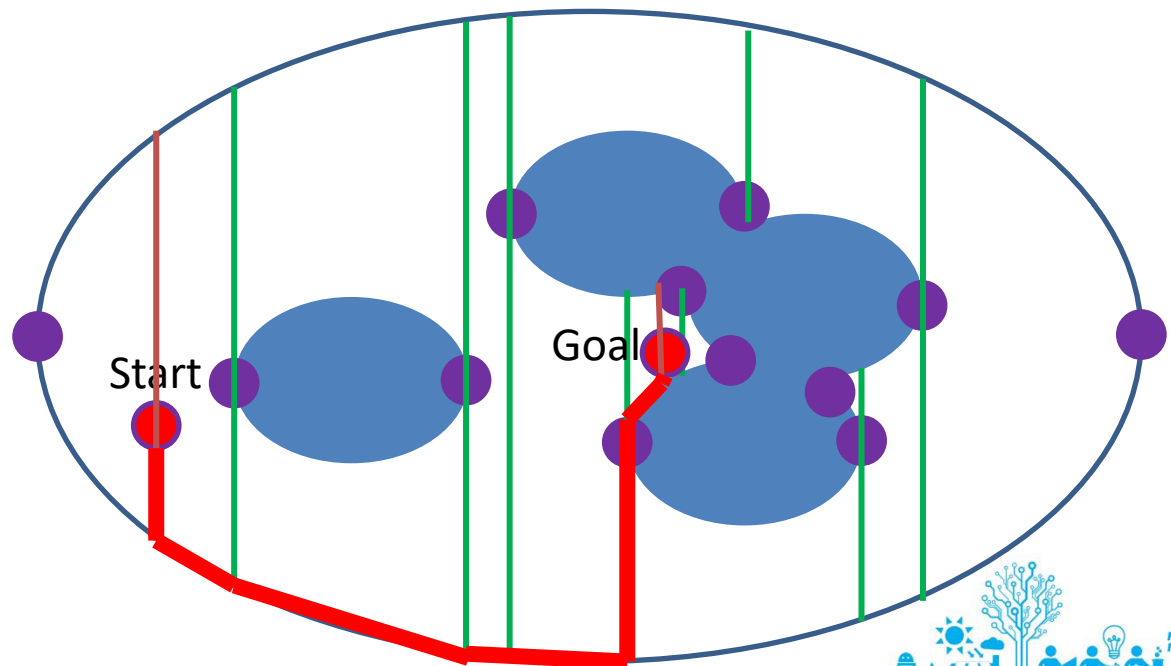

# Canny's Roadmap Algorithm

- To plan add the start and goal configurations and add lines for these

# Canny's Roadmap Algorithm

- Search the roadmap for a path from start to goal

# Pros and Cons

- Quite fast to compute roadmap
- Long detours
- Follows many obstacles/boundaries
- Obstacles as polynomials
- Works in higher dimensions

# Summary

- Roadmaps
  - Nodes correspond to collision-free configurations
  - Edges correspond to collision-free paths
  - Requirements
    - Accessibility
    - Connectivity
    - Departability
